

Chapter 14. Rectilinear Figures [Quadrilaterals: Parallelogram, Rectangle, Rhombus, Square and Trapezium]

Exercise 14(A)

Solution 1:

The sum of the interior angle = 4 times the sum of the exterior angles.

Therefore the sum of the interior angles = $4 \times 360^\circ = 1440^\circ$.

Now we have

$$(2n - 4) \times 90^\circ = 1440^\circ$$

$$2n - 4 = 16$$

$$2n = 20$$

$$n = 10$$

Thus the number of sides in the polygon is 10.

Solution 2:

Let the angles of the pentagon are $4x$, $8x$, $6x$, $4x$ and $5x$.

Thus we can write

$$4x + 8x + 6x + 4x + 5x = 540^\circ$$

$$27x = 540^\circ$$

$$x = 20^\circ$$

Hence the angles of the pentagon are:

$$4 \times 20^\circ = 80^\circ, 8 \times 20^\circ = 160^\circ, 6 \times 20^\circ = 120^\circ, 4 \times 20^\circ = 80^\circ, 5 \times 20^\circ = 100^\circ$$

Solution 3:

Let the measure of each equal angles are x .

Then we can write

$$140^\circ + 5x = (2 \times 6 - 4) \times 90^\circ$$

$$140^\circ + 5x = 720^\circ$$

$$5x = 580^\circ$$

$$x = 116^\circ$$

Therefore the measure of each equal angles are 116°

Solution 4:

Let the number of sides of the polygon is n and there are k angles with measure 195° .

Therefore we can write:

$$5 \times 90^\circ + k \times 195^\circ = (2n - 4) 90^\circ$$

$$180^\circ n - 195^\circ k = 450^\circ - 360^\circ$$

$$180^\circ n - 195^\circ k = 90^\circ$$

$$12n - 13k = 6$$

In this linear equation n and k must be integer. Therefore to satisfy this equation the minimum value of

k must be 6 to get n as integer.
Hence the number of sides are: $5 + 6 = 11$.

Solution 5:

Let the measure of each equal angles are x.

Then we can write:

$$3 \times 132^\circ + 4x = (2 \times 7 - 4)90^\circ$$

$$4x = 900^\circ - 396$$

$$4x = 504$$

$$x = 126^\circ$$

Thus the measure of each equal angles are 126° .

Solution 6:

Let the measure of each equal sides of the polygon is x.

Then we can write:

$$142^\circ + 176^\circ + 6x = (2 \times 8 - 4)90^\circ$$

$$6x = 1080^\circ - 318^\circ$$

$$6x = 762^\circ$$

$$x = 127^\circ$$

Thus the measure of each equal angles are 127° .

Solution 7:

Let the measure of the angles are 3x, 4x and 5x.

Thus

$$\angle A + \angle B + \angle C + \angle D + \angle E = 540^\circ$$

$$3x + (\angle B + \angle C) + 4x + 5x = 540^\circ$$

$$12x + 180^\circ = 540^\circ$$

$$12x = 360^\circ$$

$$x = 30^\circ$$

Thus the measure of angle E will be $4 \times 30^\circ = 120^\circ$

Solution 8:

(i)

Let each angle of measure x degree.

Therefore measure of each angle will be:

$$x = 180^0 - 2 \times 15^0 = 150^0$$

(ii)

Let each angle of measure x degree.

Therefore measure of each exterior angle will be:

$$\begin{aligned} x &= 180^0 - 150^0 \\ &= 30^0 \end{aligned}$$

(iii)

Let the number of each sides is n .

Now we can write

$$\begin{aligned} n \cdot 150^0 &= (2n - 4) \times 90^0 \\ 180^0 n - 150^0 n &= 360^0 \\ 30^0 n &= 360^0 \\ n &= 12 \end{aligned}$$

Thus the number of sides are 12.

Solution 9:

Let measure of each interior and exterior angles are $3k$ and $2k$.

Let number of sides of the polygon is n .

Now we can write:

$$\begin{aligned} n \cdot 3k &= (2n - 4) \times 90^0 \\ 3nk &= (2n - 4) 90^0 \quad \dots(1) \end{aligned}$$

Again

$$\begin{aligned} n \cdot 2k &= 360^0 \\ nk &= 180^0 \end{aligned}$$

From (1)

$$\begin{aligned} 3 \cdot 180^0 &= (2n - 4) 90^0 \\ 3 &= n - 2 \\ n &= 5 \end{aligned}$$

Thus the number of sides of the polygon is 5.

Solution 10:

For $(n-1)$ sided regular polygon:

Let measure of each angle is x .

Therefore

$$(n-1)x = (2(n-1)-4)90^\circ$$

$$x = \frac{n-3}{n-1}180^\circ$$

For $(n+1)$ sided regular polygon:

Let measure of each angle is y .

Therefore

$$(n+2)y = (2(n+2)-4)90^\circ$$

$$y = \frac{n}{n+2}180^\circ$$

Now we have

$$y - x = 6^\circ$$

$$\frac{n}{n+2}180^\circ - \frac{n-3}{n-1}180^\circ = 6^\circ$$

$$\frac{n}{n+2} - \frac{n-3}{n-1} = \frac{1}{30}$$

$$30n(n-1) - 30(n-3)(n+2) = (n+2)(n-1)$$

$$-30n + 30n + 180 = n^2 + n - 2$$

$$n^2 + n - 182 = 0$$

$$(n-13)(n+14) = 0$$

$$n = 13, -14$$

Thus the value of n is 13.

Solution 11:

(i)

Let the measure of each exterior angle is x and the number of sides is n .

Therefore we can write:

$$n = \frac{360^\circ}{x}$$

Now we have

$$x + x + 90^\circ = 180^\circ$$

$$2x = 90^\circ$$

$$x = 45^\circ$$

(ii)

Thus the number of sides in the polygon is:

$$n = \frac{360^\circ}{45^\circ}$$

$$= 8$$

Exercise 14(B)

Solution 1:

(i) True.

This is true, because we know that a rectangle is a parallelogram. So, all the properties of a parallelogram are true for a rectangle. Since the diagonals of a parallelogram bisect each other, the same holds true for a rectangle.

(ii) False

This is not true for any random quadrilateral. Observe the quadrilateral shown below.

Clearly the diagonals of the given quadrilateral do not bisect each other. However, if the quadrilateral was a special quadrilateral like a parallelogram, this would hold true.

(iii) False

Consider a rectangle as shown below.

It is a parallelogram. However, the diagonals of a rectangle do not intersect at right angles, even though they bisect each other.

(iv) True

Since a rhombus is a parallelogram, and we know that the diagonals of a parallelogram bisect each other, hence the diagonals of a rhombus too, bisect each other.

(v) False

This need not be true, since if the angles of the quadrilateral are not right angles, the quadrilateral would be a rhombus rather than a square.

(vi) True

A parallelogram is a quadrilateral with opposite sides parallel and equal.

Since opposite sides of a rhombus are parallel, and all the sides of the rhombus are equal, a rhombus is a parallelogram.

(vii) False

This is false, since a parallelogram in general does not have all its sides equal. Only opposite sides of a parallelogram are equal. However, a rhombus has all its sides equal. So, every parallelogram cannot be a rhombus, except those parallelograms that have all equal sides.

(viii) False

This is a property of a rhombus. The diagonals of a rhombus need not be equal.

(ix) True

A parallelogram is a quadrilateral with opposite sides parallel and equal.

A rhombus is a quadrilateral with opposite sides parallel, and all sides equal.

If in a parallelogram the adjacent sides are equal, it means all the sides of the parallelogram are equal, thus forming a rhombus.

(x) False

Observe the above figure. The diagonals of the quadrilateral shown above bisect each other at right angles, however the quadrilateral need not be a square, since the angles of the quadrilateral are clearly not right angles.

Solution 2:

From the given figure we conclude that

$$\angle A + \angle D = 180^\circ \text{ [since consecutive angles are supplementary]}$$

$$\frac{\angle A}{2} + \frac{\angle D}{2} = 90^\circ$$

Again from the $\triangle ADM$

$$\frac{\angle A}{2} + \frac{\angle D}{2} + \angle M = 180^\circ$$

$$\Rightarrow 90^\circ + \angle M = 180^\circ \quad \left[\text{since } \frac{\angle A}{2} + \frac{\angle D}{2} = 90^\circ \right]$$

$$\Rightarrow \angle M = 90^\circ$$

Hence $\angle AMD = 90^\circ$

Solution 3:

In the given figure

Given that $AE = BC$

We have to find $\angle AEC$ $\angle BCD$

Let us join EC and BD .

In the quadrilateral $AECB$

$AE = BC$ and $AB = EC$

also $AE \parallel BC$

$\Rightarrow AB \parallel EC$

So quadrilateral is a parallelogram.

In parallelogram consecutive angles are supplementary

$$\Rightarrow \angle A + \angle B = 180^\circ$$

$$\Rightarrow 102^\circ + \angle B = 180^\circ$$

$$\Rightarrow \angle B = 78^\circ$$

In parallelogram opposite angles are equal

$$\Rightarrow \angle A = \angle BEC \text{ and } \angle B = \angle AEC$$

$$\Rightarrow \angle BEC = 102^\circ \text{ and } \angle AEC = 78^\circ$$

Now consider $\triangle ECD$

$EC = ED = CD$ [Since $AB = EC$]

Therefore $\triangle ECD$ is an equilateral triangle.

$$\Rightarrow \angle ECD = 60^\circ$$

$$\angle BCD = \angle BEC + \angle ECD$$

$$\Rightarrow \angle BCD = 102^\circ + 60^\circ$$

$$\Rightarrow \angle BCD = 162^\circ$$

Therefore $\angle AEC = 78^\circ$ and $\angle BCD = 162^\circ$

Solution 4:

Given ABCD is a square and diagonals meet at O. P is a point on BC such that OB=BP

In the

$\triangle BOC$ and $\triangle DOC$

$\Rightarrow BD = BD$ [common side]

$\Rightarrow BO = CO$

$\angle BOD = \angle DOC$ [since diagonals cut at O]

$\triangle BOC \cong \triangle DOC$ [by SSS]

Therefore

$$\angle BOC = 90^\circ$$

NOW

$$\angle POC = 22.5^\circ$$

$$\angle BOP = 67.5^\circ \text{ [since } \angle BOC = 67.5^\circ + 22.5^\circ \text{]}$$

Again

$\triangle BDC$

$$\angle BDC = 45^\circ \text{ [since } \angle B = 45^\circ, \angle C = 90^\circ \text{]}$$

Therefore

$$\angle BDC = 2\angle POC$$

AGAIN

$$\angle BOP = 67.5^\circ$$

$$\Rightarrow \angle BOP = 2\angle POC$$

Hence proved that

$$\text{i) } \angle PC = \left(22\frac{1}{2}^\circ \right)$$

$$\text{(ii) } \angle BDC = 2 \angle POC$$

$$\text{(iii) } \angle BOP = 3 \angle CPO$$

Solution 5:

In the given figure $\triangle APB$ is an equilateral triangle

Therefore all its angles are 60°

Again in the

$\triangle ADB$

$$\angle ABD = 45^\circ$$

$$\begin{aligned}\angle AOB &= 180^\circ - 60^\circ - 45^\circ \\ &= 75^\circ\end{aligned}$$

Again

$\triangle BPC$

$$\Rightarrow \angle BPC = 75^\circ \text{ [Since } BP = CB\text{]}$$

Now

$$\begin{aligned}\angle C &= \angle BCP + \angle PCD \\ \Rightarrow \angle PCD &= 90^\circ - 75^\circ \\ \Rightarrow \angle PCD &= 15^\circ\end{aligned}$$

Therefore

$$\begin{aligned}\angle APC &= 60^\circ + 75^\circ \\ \Rightarrow \angle APC &= 135^\circ \\ \Rightarrow \text{Reflex } \angle APD &= 360^\circ - 135^\circ = 225^\circ\end{aligned}$$

$$(i) \angle AOB = 75^\circ$$

$$(ii) \angle BPC = 75^\circ$$

$$(iii) \angle PCD = 15^\circ$$

$$(iv) \text{Reflex } \angle APD = 225^\circ$$

Solution 6:

Given that the figure ABCD is a rhombus with angle $A = 67^\circ$

In the rhombus We have

$$\angle A = 67^\circ = \angle C \text{ [Opposite angles]}$$

$$\angle A + \angle D = 180^\circ \text{ [Consecutive angles are supplementary]}$$

$$\Rightarrow \angle D = 113^\circ$$

$$\Rightarrow \angle ABC = 113^\circ$$

Consider $\triangle DBC$,

$$DC = CB \text{ [Sides of rhombous]}$$

So $\triangle DBC$ is an isoscales triangle

$$\Rightarrow \angle CDB = \angle CBD$$

Also,

$$\angle CDB + \angle CDB + \angle BCD = 180^\circ$$

$$\Rightarrow 2\angle CBD = 113^\circ$$

$$\Rightarrow \angle CDB = \angle CBD = 56.5^\circ \dots\dots\dots(i)$$

Consider $\triangle DCE$,

$$EC = CB$$

So $\triangle DCE$ is an isoscales triangle

$$\Rightarrow \angle CDE = \angle CED$$

Also,

$$\angle CDE + \angle CED + \angle BCE = 180^\circ$$

$$\Rightarrow 2\angle CDE = 53^\circ$$

$$\Rightarrow \angle CDE = 26.5^\circ$$

From (i)

$$\angle CBD = 56.5^\circ$$

$$\Rightarrow \angle CBE + \angle DBE = 56.5^\circ$$

$$\Rightarrow 26.5^\circ + \angle DBE = 56.5^\circ$$

$$\Rightarrow \angle DBE = 30.5^\circ$$

Solution 7:

(i) ABCD is a parallelogram

Therefore

$$AD=BC$$

$$AB=DC$$

Thus

$$4y = 3x - 3 \quad [\text{since } AD=BC]$$

$$\Rightarrow 3x - 4y = 3 \quad (i)$$

$$6y + 2 = 4x \quad [\text{since } AB=DC]$$

$$4x - 6y = 2 \quad (ii)$$

Solving equations (i) and (ii) we have

$$x=5$$

$$y=3$$

(ii)

In the figure ABCD is a parallelogram

$$\angle A = \angle C$$

$$\angle B = \angle D \quad [\text{since opposite angles are equal}]$$

Therefore

$$7y = 6y + 3y - 8^\circ \quad (i) \quad [\text{Since } \angle A = \angle C]$$

$$4x + 20^\circ = 0 \quad (ii)$$

Solving (i), (ii) we have

$$x = 12^\circ$$

$$y = 16^\circ$$

Solution 8:

Given that the angles of a quadrilateral are in the ratio 3 : 4 : 5 : 6 Let the angles be $3x, 4x, 5x, 6x$

$$3x + 4x + 5x + 6x = 360^\circ$$

$$\Rightarrow x = \frac{360^\circ}{18}$$

$$\Rightarrow x = 20^\circ$$

Therefore the angles are

$$3 \times 20 = 60^\circ,$$

$$4 \times 20 = 80^\circ,$$

$$5 \times 20 = 100^\circ,$$

$$6 \times 20 = 120^\circ$$

Since all the angles are of different degrees thus forms a trapezium

Solution 9:

Given $AB = 20$ cm and $AD = 12$ cm.

From the above figure, it's evident that ABF is an isosceles triangle with angle $BAF = \text{angle } BFA = x$

So $AB = BF = 20$

$BF = 20$

$BC + CF = 20$

$CF = 20 - 12 = 8$ cm

Solution 10:

We know that $AQCP$ is a quadrilateral. So sum of all angles must be 360.

$$\therefore x + y + 90 + 90 = 360$$

$$x + y = 180$$

Given $x:y = 2:1$

So substitute $x = 2y$

$$3y = 180$$

$$y = 60$$

$$x = 120$$

We know that angle $C = \text{angle } A = x = 120$

$$\text{Angle } D = \text{Angle } B = 180 - x = 180 - 120 = 60$$

Hence, angles of parallelogram are 120, 60, 120 and 60.

Exercise 14(C)

Solution 1:

Let us draw a parallelogram $ABCD$ Where F is the midpoint

Of side DC of parallelogram $ABCD$

To prove: $AEDF$ is a parallelogram

Proof:

Therefore $ABCD$

$$AB \parallel DC$$

$$BC \parallel AD$$

$$AB = DC$$

$$\frac{1}{2}AB = \frac{1}{2}DC$$

$$AE = DF$$

Also $AD \parallel EF$

therefore $AEDF$ is a parallelogram.

Solution 2:

GIVEN: $ABCD$ is a parallelogram where the diagonal BD bisects

parallelogram $ABCD$ at angle B and D

TO PROVE: $ABCD$ is a rhombus

Proof : Let us draw a parallelogram $ABCD$ where the diagonal BD bisects the parallelogram at angle B and D

Construction : Let us join AC as a diagonal of the parallelogram

$ABCD$

Since $ABCD$ is a parallelogram

Therefore

$$AB = DC$$

$$AD = BC$$

Diagonal BD bisects angle B and D

$$\text{So } \angle COD = \angle DOA$$

Again AC also bisects at A and C

$$\text{Therefore } \angle AOB = \angle BOC$$

Thus $ABCD$ is a rhombus.

Solution 3:

Given $ABCD$ is a parallelogram and $AE=EF=FC$.

We have to prove at first that $DEBF$ is a parallelogram.

Proof: From $\triangle ADE$ and $\triangle BCF$

$$AE=FC$$

$$AD=BC$$

$$\angle D = \angle B$$

$$\triangle ADE \cong \triangle BCF \quad [\text{SAS}]$$

Therefore $DE=FB$

$$DC=EF \quad [\text{since } AE+EF+FC=AC \text{ and } AE=EF=FC]$$

Therefore $DEBF$ is a parallelogram.

So $DE \parallel FB$

Hence proved

Solution 4:

Let us join PQ.

Consider the $\triangle AOQ$ and $\triangle BOP$

$$\angle AOQ = \angle BOP \quad [\text{opposite angles}]$$

$$\angle OAQ = \angle BPO \quad [\text{alternate angles}]$$

$$\Rightarrow \triangle AOQ \cong \triangle BOP \quad [\text{AA test}]$$

$$\text{Hence } AQ = BP$$

Consider the $\triangle QOP$ and $\triangle AOB$

$$\angle AOB = \angle QOP \quad [\text{opposite angles}]$$

$$\angle OAB = \angle OPQ \quad [\text{alternate angles}]$$

$$\Rightarrow \triangle QOP \cong \triangle AOB \quad [\text{AA test}]$$

$$\text{Hence } PQ = AB = CD$$

Consider the quadrilateral $QPCD$

$$DQ = CP \text{ and } DQ \parallel CP \quad [\text{Since } AD = BC \text{ and } AD \parallel BC]$$

$$\text{Also } QP = DC \text{ and } AB \parallel QP \parallel DC$$

Hence quadrilateral $QPCD$ is a parallelogram.

Solution 5:

Given $ABCD$ is a parallelogram

To prove: $AB = 2BC$

Proof: $ABCD$ is a parallelogram

$$\angle A + \angle D = \angle B + \angle C = 180^\circ$$

From the $\triangle AEB$ we have

$$\Rightarrow \frac{\angle A}{2} + \frac{\angle B}{2} + \angle E = 180^\circ$$

$$\Rightarrow \angle A - \frac{\angle A}{2} + \angle D + \angle E1 = 180^\circ \quad [\text{taking } E1 \text{ as new angle}]$$

$$\Rightarrow \angle A + \angle D + \angle E1 = 180^\circ + \frac{\angle A}{2}$$

$$\Rightarrow \angle E1 = \frac{\angle A}{2} \quad [\text{Since } \angle A + \angle D = 180^\circ]$$

Again,

similarly,

$$\angle E2 = \frac{\angle B}{2}$$

NOW

$$AB = DE + EC$$

$$= AD + BC$$

$$= 2BC \quad [\text{since } AD = BC]$$

Hence proved

Solution 6:

Given $ABCD$ is a parallelogram. The bisectors of $\angle ADC$ and $\angle BCD$ meet at E. The bisectors of $\angle ABC$ and $\angle BCD$ meet at F

From the parallelogram $ABCD$ we have

$$\angle ADC + \angle BCD = 180^\circ \text{ [sum of adjacent angles of a parallelogram]}$$

$$\Rightarrow \frac{\angle ADC}{2} + \frac{\angle BCD}{2} = 90^\circ$$

$$\Rightarrow \angle EDC + \angle ECD = 90^\circ$$

In triangle ECD sum of angles = 180°

$$\Rightarrow \angle EDC + \angle ECD + \angle CED = 180^\circ$$

$$\Rightarrow \angle CED = 90^\circ$$

Similarly taking triangle BCF it can be prove that $\angle BFC = 90^\circ$

Now since

$$\angle BFC = \angle CED = 90^\circ$$

Therefore the lines DE and BF are parallel

Hence proved

Solution 7:

Given: $ABCD$ is a parallelogram

AE bisects $\angle BAD$

BF bisects $\angle ABC$

CG bisects $\angle BCD$

DH bisects $\angle ADC$

TO PROVE: $LKJI$ is a rectangle

Proof :

$\angle BAD + \angle ABC = 180^\circ$ [adjacent angles of a parallelogram are supplementary]

$\angle BAJ = \frac{1}{2} \angle BAD$ [AE bisects $\angle BAD$]

$\angle ABJ = \frac{1}{2} \angle ABC$ [DH bisect $\angle ABC$]

$\angle BAJ + \angle ABJ = 90^\circ$ [halves of supplementary angles are complementary]

$\triangle ABJ$ is a right triangle because its acute interior angles are complementary.

Similarly

$\angle DLC = 90^\circ$

$\angle AID = 90^\circ$

Then $\angle JIL = 90^\circ$ because $\angle AID$ and $\angle JIL$ are vertical angles

since 3 angles of quadrilateral $LKJI$ are right angles, so is the 4th one and so $LKJI$ is a rectangle, since its interior angles are all right angles

Hence proved

Solution 8:

Given: A parallelogram $ABCD$ in which AR, BR, CP, DP

Are the bisectors of $\angle A, \angle B, \angle C, \angle D$ respectively forming quadrilaterals $PQRS$.

To prove: $PQRS$ is a rectangle

Proof:

$$\angle DCB + \angle ABC = 180^\circ \text{ [co-interior angles of parallelogram are supplementary]}$$

$$\Rightarrow \frac{1}{2} \angle DCB + \frac{1}{2} \angle ABC = 90^\circ$$

Also in

$$\Rightarrow \angle 1 + \angle 2 = 90^\circ$$

$$\triangle CQB, \angle 1 + \angle 2 + \angle CQB = 180^\circ$$

From the above equation we get

$$\angle CQB = 180^\circ - 90^\circ = 90^\circ$$

$$\angle RQP = 90^\circ \text{ [}\angle CQB = \angle RQP, \text{vertically opposite angles]}$$

$$\angle QRP = \angle RSP = \angle SPQ = 90^\circ$$

Hence $PQRS$ is a rectangle

Solution 9:

(i) Let $AD = x$

$$AB = 2AD = 2x$$

Also AP is the bisector $\angle A$

$$\angle 1 = \angle 2$$

Now,

$$\angle 2 = \angle 5 \text{ [alternate angles]}$$

Therefore $\angle 1 = \angle 5$

Now

$$AP = DP = x \text{ [sides opposite to equal angles are also equal]}$$

Therefore

$$AB=CD \text{ [opposite sides of parallelogram are equal]}$$

$$CD = 2x$$

$$\Rightarrow DP+PC=2x$$

$$\Rightarrow x+PC=2x$$

$$\Rightarrow PC = x$$

$$\text{Also, } BC=x$$

$$\triangle BPC$$

$$\text{In } \Rightarrow \angle 6 = \angle 4 \text{ [angles opposite to equal sides are equal]}$$

$$\Rightarrow \angle 6 = \angle 3$$

$$\text{Therefore } \angle 3 = \angle 4$$

$$\text{Hence } BP \text{ bisect } \angle B$$

(ii)

Opposite angles are supplementary

Therefore

$$\angle 1 + \angle 2 + \angle 3 + \angle 4 = 180^\circ$$

$$\Rightarrow 2\angle 2 + 2\angle 3 = 180^\circ \begin{bmatrix} \angle 1 = \angle 2 \\ \angle 3 = \angle 4 \end{bmatrix}$$

$$\Rightarrow \angle 2 + \angle 3 = 90^\circ$$

$$\triangle APB$$

$$\angle 2 + \angle 3 + \angle APB = 180^\circ$$

$$\Rightarrow \angle APB = 180^\circ - 90^\circ \text{ [by angle sum property]}$$

$$\Rightarrow \angle APB = 90^\circ$$

Hence proved

Solution 10:

Points M and N are taken on the diagonal AC of a parallelogram $ABCD$ such that $AM=CN$.

Prove that $BMDN$ is a parallelogram

CONSTRUCTION: Join B to D to meet AC in O .

PROOF: We know that the diagonals of parallelogram bisect each other.

Now, AC and BD bisect each other at O .

$$OC=OA$$

$$AM=CN$$

$$\Rightarrow OA-AM=OC-CN$$

$$\Rightarrow OM=ON$$

Thus in a quadrilateral $BMDN$, diagonal BD and MN are such that $OM=ON$ and $OD=OB$

Therefore the diagonals AC and PQ bisect each other.

Hence $BMDN$ is a parallelogram

Solution 11:

Consider $\triangle ADP$ and $\triangle BCP$

$AD=BC$ [since ABCD is a parallelogram]

$DC=AB$ [since ABCD is a parallelogram]

$\angle A = \angle C$ [opposite angles]

$\triangle ADP \cong \triangle BCP$ [SAS]

Therefore $AP=BP$

AP bisects $\angle A$

BP bisects $\angle B$

In $\triangle APB$

$AP=PB$

$\angle APB = \angle DAP + \angle BCP$

Hence proved

Solution 12:

ABCD is a square and $AQ = BP$

Consider $\triangle DAQ$ and $\triangle ABP$

$$\angle DAQ = \angle ABP = 90^\circ$$

$$DQ = AP$$

$$AD = AB$$

$$\triangle DAQ \cong \triangle ABP$$

$$\Rightarrow \angle PAB = \angle QDA$$

Now,

$$\angle PAB + \angle APB = 90^\circ$$

$$\text{also } \angle QDA + \angle APB = 90^\circ \quad [\angle PAB = \angle QDA]$$

Consider $\triangle AOD$ By ASP

$$\angle QDA + \angle APB + \angle AOD = 180^\circ$$

$$\Rightarrow 90^\circ + \angle AOD = 180^\circ$$

$$\Rightarrow \angle AOD = 90^\circ$$

Hence AP and DQ are perpendicular.

Solution 13:

Given: $ABCD$ is quadrilateral,

$$AB=AD$$

$$CB=CD$$

To prove: (i) AC bisects angle BAD .

(ii) AC is perpendicular bisector of BD .

Proof :

In $\triangle ABC$ and $\triangle ADC$

$$AB=AD \text{ [given]}$$

$$CB=CD \text{ [given]}$$

$$AC=AC \text{ [common side]}$$

$$\triangle ABC \cong \triangle ADC \text{ [SSS]}$$

Therefore AC bisects $\angle BAD$

$$OD=OB$$

$$OA=OA \text{ [diagonals bisect each other at O]}$$

Thus AC is perpendicular bisector of BD

Hence proved

Solution 14:

Given $ABCD$ is a trapezium, $AB \parallel DC$ and $AD=BC$

To prove (i) $\angle DAB = \angle CBA$

(ii) $\angle ADC = \angle BCD$

(iii) $AC = BD$

(iv) $OA = OB$ and $OC = OD$

Proof : (i) Since $AD \parallel CE$ and transversal AE cuts them at A and E respectively.

Therefore, $\angle A + \angle B = 180^\circ$

Since $AB \parallel CD$ and $AD \parallel BC$

Therefore $ABCD$ is a parallelogram

$$\angle A = \angle C$$

$$\angle B = \angle D \text{ [since } ABCD \text{ is a parallelogram]}$$

$$\text{Therefore } \angle DAB = \angle CBA$$

$$\angle ADC = \angle BCD$$

In $\triangle ABC$ and $\triangle BAD$, we have

$$BC=AD \text{ [given]}$$

$$AB=BA \text{ [common]}$$

$$\angle A = \angle B \text{ [proved]}$$

$$\triangle ABC \cong \triangle BAD \text{ [SAS]}$$

$$\text{Since } \triangle ABC \cong \triangle BAD$$

$$\text{Therefore } AC=BD \text{ [corresponding parts of congruent triangles are equal]}$$

$$\text{Again } OA=OB$$

$$OC=OD \text{ [since diagonals bisect each other at } O]$$

Hence proved

Solution 15:

Join AC to meet BD in O

We know that the diagonals of a parallelogram bisect each other. Therefore AC and BD bisect each other at O.

Therefore

$$OB = OD$$

But

$$BQ = DP$$

$$OB - PQ = OD - DP$$

$$\Rightarrow OQ = OP$$

Thus in a quadrilateral APCQ diagonals AC and PQ such that $OQ = OP$ and $OA = OC$. Since diagonals AC and PQ bisect each other.

Hence APCQ is a parallelogram

Solution 16:

ABCD is a parallelogram, the bisectors of $\angle ADC$ and $\angle BCD$ meet at a point E and the bisectors of $\angle BCD$ and $\angle ABC$ meet at F.

We have to prove that the $\angle CED = 90^\circ$ and $\angle CFG = 90^\circ$

Proof: In the parallelogram ABCD

$$\angle ADC + \angle BCD = 180^\circ \text{ [sum of adjacent angles of a parallelogram]}$$

$$\Rightarrow \frac{\angle ADC}{2} + \frac{\angle BCD}{2} = 90^\circ$$

$$\Rightarrow \angle EDC + \angle ECD + \angle CED = 180^\circ$$

$$\Rightarrow \angle CED = 90^\circ$$

Similarly taking triangle BCF it can be proved that $\angle BFC = 90^\circ$

$$\text{Also } \angle BFC + \angle CFG = 180^\circ \text{ [adjacent angles on a line]}$$

$$\Rightarrow \angle CFG = 90^\circ$$

Now since $\angle CFG = \angle CED = 90^\circ$ [it means that the lines DE and BF are parallel]

Hence proved

Solution 17:

To prove : ABCD is a square,
 that is, to prove that sides of the quadrilateral are equal
 and each angle of the quadrilateral is 90° .
 ABCD is a rectangle,
 $\Rightarrow \angle A = \angle B = \angle C = \angle D = 90^\circ$ and diagonals bisect each other
 that is, $MD = BM \dots (i)$
 Consider $\triangle AMD$ and $\triangle AMB$,
 $MD = BM$ (from (i))
 $\angle AMD = \angle AMB = 90^\circ$ (given)
 $AM = AM$ (common side)
 $\triangle AMD \cong \triangle AMB$ (SAS congruence criterion)
 $\Rightarrow AD = AB$ (cpctc)
 Since ABCD is a rectangle, $AD = BC$ and $AB = CD$
 Thus, $AB = BC = CD = AD$ and $\angle A = \angle B = \angle C = \angle D = 90^\circ$
 $\Rightarrow$ ABCD is a square.

Solution 18:

ABCD is a parallelogram
 $\Rightarrow$ opposite angles of a parallelogram are congruent
 $\Rightarrow \angle DAB = \angle BCD$ and $\angle ABC = \angle ADC = 120^\circ$
 In ABCD,
 $\angle DAB + \angle BCD + \angle ABC + \angle ADC = 360^\circ$
 $\dots\dots\dots$ (sum of the measures of angles of a quadrilateral)
 $\Rightarrow \angle BCD + \angle BCD + 120^\circ + 120^\circ = 360^\circ$
 $\Rightarrow 2\angle BCD = 360^\circ - 240^\circ$
 $\Rightarrow 2\angle BCD = 120^\circ$
 $\Rightarrow \angle BCD = 60^\circ$
 PQRS is a parallelogram
 $\Rightarrow \angle PQR = \angle PSR = 70^\circ$
 In $\triangle CMS$,
 $\angle CMS + \angle CSM + \angle MCS = 180^\circ \dots\dots$ (angle sum property)
 $\Rightarrow x + 70^\circ + 60^\circ = 180^\circ$
 $\Rightarrow x = 50^\circ$

Solution 19:

ABCD is a rhombus $\Rightarrow AD = CD$ and $\angle ADC = \angle ABC = 56^\circ$

DCFE is a square $\Rightarrow ED = CD$ and $\angle FED = \angle EDC = \angle DCF = \angle CFE = 90^\circ$

$\Rightarrow AD = CD = ED$

In $\triangle ADE$,

$AD = ED \Rightarrow \angle DAE = \angle AED \dots (i)$

$\angle DAE + \angle AED + \angle ADE = 180^\circ$

$\Rightarrow 2\angle DAE + 146^\circ = 180^\circ \dots (\text{Since } \angle ADE = \angle EDC + \angle ADC = 90^\circ + 56^\circ = 146^\circ)$

$\Rightarrow 2\angle DAE = 34^\circ$

$\Rightarrow \angle DAE = 17^\circ$

$\Rightarrow \angle DEA = 17^\circ \dots (ii)$

In ABCD,

$\angle ABC + \angle BCD + \angle ADC + \angle DAB = 360^\circ$

$\Rightarrow 56^\circ + 56^\circ + 2\angle DAB = 360^\circ \quad (\because \text{opposite angles of a rhombus are equal})$

$\Rightarrow 2\angle DAB = 248^\circ$

$\Rightarrow \angle DAB = 124^\circ$

We know that diagonals of a rhombus bisect its angles.

$\Rightarrow \angle DAC = \frac{124^\circ}{2} = 62^\circ$

$\Rightarrow \angle EAC = \angle DAC - \angle DAE = 62^\circ - 17^\circ = 45^\circ$

Now, $\angle FEA = \angle FED - \angle DEA$

$= 90^\circ - 17^\circ \dots (\text{from (ii) and each angle of a square is } 90^\circ)$

$= 73^\circ$

We know that diagonals of a square bisect its angles.

$\Rightarrow \angle CED = \frac{90^\circ}{2} = 45^\circ$

So, $\angle AEC = \angle CED - \angle DEA$

$= 45^\circ - 17^\circ$

$= 28^\circ$

Hence, $\angle DAE = 17^\circ$, $\angle FEA = 73^\circ$, $\angle EAC = 45^\circ$ and $\angle AEC = 28^\circ$.
